Abstract

Chylothorax after coronary artery bypass grafting is a rare complication and leads to increased mortality and morbidity. Because of the rarity of this complication, its management is debatable. We present the case of a 41 years old male patient who had a left sided chylothorax after coronary artery bypass grafting. The patient was managed conservatively with low fat diet and drainage of the chylothorax. A thorough search of the literature published on the subject was done and treatment strategies employed by various authors were studied. Various treatment options are conservative management with chest tube drainage, octreotide and low-fat diet or diet containing medium chain triglycerides. Invasive options are video assisted thoracoscopy and thoracotomy with or without ligation of thoracic duct. An account of the management strategies employed by various authors is presented in this report.

Keywords: Chylothorax, Coronary artery bypass grafting, Management

1. Introduction

Chylothorax is the presence of lymphatic fluid, or chyle, in the thoracic cavity. The incidence of chylothorax is 0.4–4% in esophageal procedures to 2.5%–4.7% in congenital cardiac procedures [1,2]. But chylothorax after coronary artery bypass grafting has been described very rarely. This is probably because lymphatics are valved and normally these valves are competent. Also the anatomy of the thoracic duct keeps it safe in surgical revascularization. In most cases the thoracic duct traverses up the chest on the right side of the aorta and at the level of T4-T5 travels to the left side ascending in the chest and then projects for a short while into the neck. It ends by entering the junction of subclavian vein and internal jugular vein by curving down. But this ‘normal’ course is found in

only 50–60% of the population and in 12–15% cases, there is anomalous course and aberrant tributaries of the duct [3]. The left anterior mediastinal lymph node chain crosses the left internal mammary artery (LIMA) anteriorly near its origin. It joins the thoracic duct or in some cases, enters the venous confluence directly. This chain is vulnerable to injury during harvesting of LIMA, especially if the mammary vein is divided proximally [4]. Injury to anomalous peri-thymic lymphatics and use of electrocautery in lymphatic rich area rather than suturing for hemostasis are some of the mechanisms [5]. Because of the rarity of chylothorax after CABG, there is no consensus on the management strategy. This report describes the case of chylothorax after CABG and sheds light on the previously reported cases and management strategies.

2. Case report

A 41 years old gentleman, known diabetic and hypertensive, presented with chest pain, palpitations and diaphoresis. He was diagnosed to have non-ST elevation myocardial infarction and a subsequent coronary angiography showed multivessel coronary artery disease. The patient was scheduled for elective coronary artery bypass grafting. The CABG included a pedicled LIMA to left anterior descending (LAD) artery, great saphenous vein to right coronary artery (RCA), obtuse marginal (OM) and diagonal coronary arteries. Left pleura was widely opened during harvesting of the LIMA and thymus was dissected with electrocautery. The patient had an uneventful postoperative course and discharged on the 10th day.

Just 3 days after discharge, the patient presented with shortness of breath and tiredness. On examination, breath sounds were greatly diminished on left side of the chest. A postero-anterior chest X-Ray was done that showed large left sided pleural effusion [Fig. 1](#).

Chest drain was inserted that drained 2400 ml milk colored fluid.

The patient rapidly improved symptomatically with drainage of the effusion. A Gram staining and Ziel Nelson staining of the pleural fluid did not show any organism. But the initial biochemical analysis showed triglyceride of 1575 mg/dl (normal <110 mg/dl) and cholesterol less than 50 mg/dl. Chylothorax was diagnosed and the patient was rendered nil by mouth and total parenteral nutrition was started. The chest tube drainage dropped to 1000 ml on the second day, 600 ml on the third and 300 ml on fourth day. A low-fat diet was then started. The drainage

decreased further and the tube was removed on day seventh. The patient was then discharged with clear both lung fields and in a normal and stable condition. One month later, the patient was asymptomatic and chest X-Ray showed no pleural effusion ([Fig. 2](#)).

3. Discussion

Chylothorax after coronary artery bypass grafting poses a unique problem. If it doesn't respond to conservative management, invasive management must be adopted. This complication can lead to deleterious consequences like immunosuppression, dehydration, malnutrition and respiratory dysfunction in a patient who is already recovering from a major open-heart surgery [6]. But luckily, the incidence is rare [1]. A thorough search of the available English language literature identified less than 50 cases. Various strategies have been used to manage this complication including a conservative approach with chest tube drainage and dietary changes, pharmacologic management with the use of somatostatin and its analogues and invasive management that involves thoracotomy or thoracoscopy to control the chyle leakage.

3.1. Conservative management

Conservative management involves nil per os (NPO), total parenteral nutrition, chest tube drainage of the chyle, and later when the drainage has decreased significantly, starting a low-fat diet or

Fig. 1. Chest X-Ray showing left sided pleural effusion.

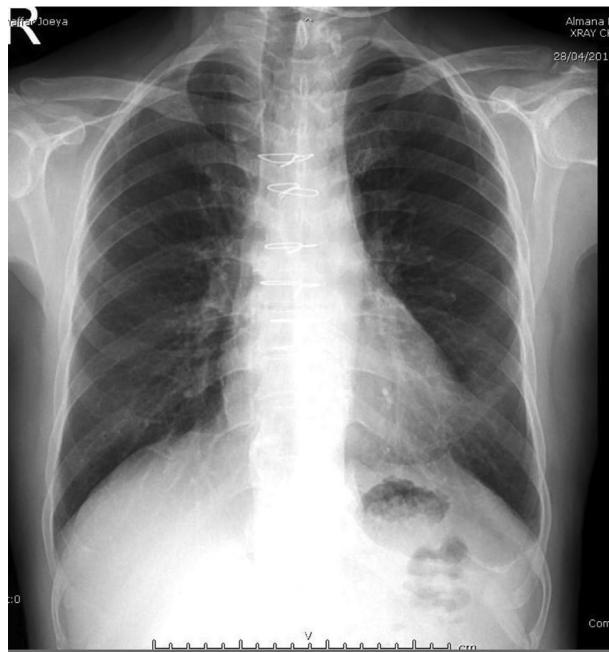

Fig. 2. Chest X-Ray on follow up.

a diet rich in medium chain triglycerides (MCTG). Most of the authors seem to have employed this regimen (**Table 1**). Excluding long chain triglycerides from the diet ensures a decreased chylomicron transportation to the intestinal lymphatic ducts. It has been suggested that a 10–14 days trial of conservative management is plausible. In case the drainage persists beyond this, invasive strategy should be followed [7]. Some of the disadvantages of conservative management are deterioration in nutritional status and vulnerability to infections because of depletion of lymphocytes.

3.2. Octreotide

Octreotide is a synthetic analogue of somatostatin which inhibits growth hormones, glucagon and insulin, more potently than somatostatin. It has been used with success in GI fistulae. The use of Octreotide for post CABG chylothorax seems to have increased recently [24]. Most authors have used a dose of 50–100 µg subcutaneously for 10–14 days. If somatostatin is used, it must be used intravenously because of its short half-life [6]. Side

effects such as hypoglycemia and hypotension should be looked for when treating patients with octreotide. The exact mechanism of action is not known but receptors having high affinity for somatostatin have been described on human lymphatics [25]. **Table 2** presents a summary of the published cases where octreotide was used.

3.3. Invasive management

Invasive options are VATS, thoracotomy, median sternotomy. Most authors agree suggest that surgery should not be delayed for more than 1–2 weeks or the output remains more than 1000 ml/day [7,27]. Historically, lymphangiography and high fat content food has been administered before the invasive procedure to localize the leaking site. But high fat content food has been shown to be preferable because the ducts damaged mostly in CABG are small in size [33]. Various strategies during invasive management are duct ligation, pleural flap cover, biological sealants and suturing of the leaking area [7]. If a delayed diagnosis is made, lavage and pleurodesis should be done through VATS because

Altun et al., 2015 [6]	CABG	60 y/M	LIMA	UK	2	Chest tube drainage, NPO, TPN, Somatostatin infusion @ 3.5 µg/kg/Hr, increased to 7 µg/Kg/Hr, resolved after 13 days
Altun et al., 2015 [6]	CABG	46 y/M	LIMA	UK	3	Chest tube drainage, NPO, TPN, Somatostatin infusion, resolved after 7 days
Owais et al., 2015 [31]	CABG	76 y/F	LIMA	L	15	Chest tube drainage, MCTG, Octreotide (100 µg SC 8 hourly), resolved after 7 days
Waikar et al., 2018 [24]	CABG	52 y/M	LIMA	L	6	Chest tube drainage, NPO, TPN, later on MCTG, Octreotide (100 µg SC 8 hourly), pleurodesis done with 7.5% povidone iodine on POD 11th, resolved after 14 days
Mukherjee et al., 2016 [32]	CABG	56 y/M	LIMA	L	3	Chest tube drainage, Octreotide, Tal pleurodesis after 30 days of conservative management, lung expanded after two days of pleurodesis
Mukherjee et al., 2016 [32]	CABG	50 y/M	LIMA	L	14	Chest tube drainage, Octreotide, Tal pleurodesis after 29 days of conservative management

Table 3. A summary of the reported cases of invasive management of chylothorax after coronary artery bypass grafting.

Author	Procedure	Age/ Gender	LIMA/ RIMA	Site	Surgery to diagnosis duration (days)	Management
Dilello et al., 1987 [36]	CABG	53 y/M	LIMA	L	9	Chest tube on POD 13th, supraclavicular approach to thoracic duct, multiple entries of TD to the vein were noticed, leakage ligated, drainage did not decrease so a left thoracotomy was done on POD 31, a diffuse leak from adhesion in the junctional area of mammary pedicle, subclavian vein and artery was noted, pleural flap was raised and the area sprayed with biological glue, the flap closed over the area, chyle drainage resolved after POD 7
Czarnecki et al., 1988 [37]	CABG	61 y/F	LIMA and RIMA	R	42	Conservative management failed after 10 days, right thoracotomy and ligation of the duct at diaphragm
Chaiyaroji et al., 1991 [38]	CABG	69 y/F	LIMA	L	6	Conservative management failed after 18 days, left thoracotomy and clipping at the leakage site
Inderbitzi et al., 1992 [39]	Redo-CABG	69 y/M	UK	L	2	Left VATS, fibrin glue spray
Bogers et al., 1993 [7]	CABG	41 y/M	LIMA	L	1	Conservative management failed after 35 days, left thoracotomy and ligation at injury site
Wood et al., 1994 [40]	CABG	69 y/M	LIMA	L	3	Conservative failed after 7 days, left VATS ligation at injury site (proximal LIMA)
Janssen et al., 1994 [41]	CABG	58 y/M	LIMAL	L	35	Conservative failed after 2 weeks, left VATS and clipping of thoracic duct behind the aortic arch
Yamaguchi et al., 1996 [42]	CABG	64 y/M	LIMA	L	2	Conservative management failed after 3 weeks, left thoracotomy

(continued on next page)

Table 3. (continued)

Author	Procedure	Age/ Gender	LIMA/ RIMA	Site	Surgery to diagnosis duration (days)	Management
Felz et al., 1997 [43]	CABG	50 y/F	LIMA	L	56	Left VATS ligation at injury site
Pego-Fernandez et al., 1997 [34]	CABG	38 y/M	LIMA	L	90	VATS for cleaning and lavage of thorax only
Venturini et al., 1999 [44]	CABG	67 y/M	LIMA	L	70	Left thoracotomy, ligation of the duct
Fahimi et al., 2001 [18]	CABG	49 y/M	LIMA	L	UK	Left VATS, fibrin glue
Riquet et al., 2004 [45]	CABG	59 y/F	LIMA	L	UK	Left thoracotomy, ligation at injury site (left anterior mediastinal lymph node chain)
Falode et al., 2005 [46]	CABG + ASD repair	68 y/F	LIMA	L	3	Left VATS, Talc pleurodesis
Choong et al., 2006 [4]	CABG	63 y/M	LIMA	L	2	Conservative management failed after 35 days, right thoracotomy and ligation at injury site (severed duct identified in thymic area)
Paul et al., 2009 [35]	CABG	65 y/M	UK	UK	UK	Conservative failed after 14 days, right thoracotomy and duct ligation at diaphragm
Deguchi et al., 2015 [47]	CABG	78 y/F	LIMA and RIMA	R	3	Conservative failed after 10 days, median sternotomy and ligation at injury site (injured lymphatic on right side of innominate vein)
Walany et al., 2018 [48]	CABG	62 y/M	LIMA	L	13	Chest tube drainage, MCTG followed by TPN, thoracoscopic Talc pleurodesis on POD 33 but drainage remained high, so Doxycycline pleurodesis through chest tube on POD 40, course complicated by Yellow Nail Syndrome, resolved ultimately

adhesions in the area of thoracic duct following surgery will make dissection in this area very difficult and dangerous [34]. Most authors have preferred a left thoracotomy or VATS and clipping or ligation of the leakage area but a right thoracotomy and mass ligation of the duct at the diaphragm has also been done [35]. Table 3.

4. Conclusion

Chylothorax is a rare complication after coronary artery bypass grafting. Patients with a pedicled harvesting of left internal mammary artery harvesting are more prone to this complication. It appears from the published reports that most of the patients can be managed with a conservative management. In case of failure of conservative management, early invasive strategy should be resorted to avoid complications.
